11 **ABSTRACT**

1  
2  
3 12 *WUSCHEL-RELATED HOMEobox (WOX)* genes are key players controlling stem cells in  
4 13 plants and can be divided into three clades according to the time of their appearance during  
5 14 plant evolution. Our knowledge of stem cell function in vascular plants other than angiosperms  
6 15 is limited, they separated from gymnosperms ca 300 million years ago and their patterning  
7 16 during embryogenesis differs significantly. For this reason, we have used the model  
8 17 gymnosperm *Pinus pinaster* to identify *WOX* genes and perform a thorough analysis of their  
9 18 gene expression patterns. Using transcriptomic data from a comprehensive range of tissues and  
10 19 stages of development we have shown three major outcomes: that the *P. pinaster* genome  
11 20 encodes at least fourteen members of the *WOX* family spanning all the major clades, that the  
12 21 genome of gymnosperms contains a *WOX* gene with no homologues in angiosperms  
13 22 representing a transitional stage between intermediate- and WUS-clade proteins, and that we  
14 23 can detect discrete *WUS* and *WOX5* transcripts for the first time in a gymnosperm.

24 **Highlights**

- 25 • *Pinus pinaster* genome encodes at least fourteen members of the *WOX* family spanning  
26 all the major clades
- 27 • Discrete *WUS* and *WOX5* transcripts were detected for the first time in a gymnosperm
- 28 • The genome of gymnosperms contains a *WOX* gene, *WOXX*, with no homologues in  
29 angiosperms representing a transitional evolutionary stage from intermediate- to WUS-  
30 clade proteins

33 embryogenesis, shoot apex, *WOX* phylogeny, *WUSCHEL-RELATED HOMEobox*

## 1. INTRODUCTION

Homeobox (HB) proteins are a superfamily of transcription factors containing a DNA-binding homeodomain (HD), which is a conserved 60-amino acid motif. Evolutionary studies indicate that the different families of HB transcription factors have diverged prior to the separation of the branches leading to animals, plants and fungi [1]. In plants, they have been recently classified into 14 classes: homeodomain-leucine zipper (HD-ZIP) classes I to IV, BEL-like (BEL), KNOTTED1-like homeobox (KNOX), plant zinc finger (PLINC), WUSCHEL-related homeobox (WOX), Plant homeodomain (PHD), DDT, Nodulin Homeobox genes (NDX), Luminidependens (LD), SAWADEE and Plant Interactor Homeobox (PINTOX) [2]. HB transcription factors participate in a great variety of processes during plant growth and development, such as determination of cell fate, cell differentiation, morphogenesis or responses to stress among others. Members of the WOX family play important roles in key developmental processes, such as embryonic patterning, stem-cell maintenance and organ formation [3-5]. Some members of the plant-specific WOX protein family can act both as activators and repressors depending on tissue type or developmental stage [6, 7].

The genome of *Arabidopsis* (*Arabidopsis thaliana*) contains 15 WOX genes. The WOX gene family has been divided into three major clades: the WUSCHEL (WUS) clade (*AtWUS* and *AtWOX1-7*), specific to ferns and seed plants; the intermediate clade (*AtWOX8, 9, 11* and *12*), present in vascular plants; and the ancient clade (*AtWOX10, 13*, and *14*), with representatives in the earliest diverging green plants and therefore probably derived from an ancestral WOX gene [4]. The role of the WOX genes during plant development has been studied in some angiosperms, such as *Arabidopsis*, *Petunia hybrida*, *Zea mays*, *Oryza sativa* and *Populus tomentosa* [3, 8-11]. However, little information is available in conifers. All WOX genes examined show very specific expression patterns, both spatially and temporally, which are important for their functions. Members of the ancient clade are expressed all over (roots, shoots and reproductive organs) and developmental stages [12]. WOX genes belonging to the intermediate clade, as well as WOX2 belonging to the WUS clade, are preferentially expressed during embryo development [13]. Some members of the WUS clade are involved in stem-cell regulation. In *Arabidopsis*, *AtWUS* is expressed in the organizing center (OC) and is involved in the maintenance of the shoot apical meristem (SAM) by a regulatory loop with *CLAVATA*, while *AtWOX5* is involved in the maintenance of the root apical meristem (RAM) [14, 15]. *AtWOX4* is involved in the cambial meristem differentiation [16], while *AtWOX3/PRSI* is involved in lateral organ development through recruiting organ founder cells forming the lateral domain [17, 18]. This functional divergence appears to have resulted primarily from the

68 evolution of divergent expression patterns, as many studies have shown that most of the WUS-  
69 clade members are interchangeable in the *Arabidopsis* SAM [11, 15, 18, 19].

70 *Arabidopsis* has been widely used as a model organism for studies in plants [20]. Gymnosperm  
71 and angiosperm species, which have a common ancestor ca 300 million years ago [21, 22],  
72 share many morphological and physiological features. However, there are key differences, such  
73 as the patterning during embryogenesis, which may alter the underlying genetic programs.  
74 Therefore, it is not known whether the model of genic expression during angiosperm  
75 development may be applicable to conifers. Several studies suggest that the *WOX* gene family  
76 may be involved in the evolution of developmental processes [8, 12, 23]. Thus, analysis of the  
77 tissue-specific expression of *WOX* genes using other model species outside the angiosperms are  
78 needed to elucidate similarities and differences in the regulatory mechanisms of plant  
79 development.

80 Recent works in conifers have shown functional conservation for some *WOX* genes. *AtWOX8*,  
81 *AtWOX9* and *AtWOX2* play important roles during the patterning and morphogenesis of the  
82 early embryo in *Arabidopsis* [13, 24]. Their orthologues in the conifer *Picea abies* *PaWOX8/9*  
83 and *PaWOX2* have similar functions [25, 26]. *PaWOX3*, the orthologue of *AtWOX3*, has been  
84 shown to play an important role in lateral organ outgrowth [27]. Despite the functional  
85 conservation of some *WOX* genes between angiosperms and gymnosperms, previous reports in  
86 gymnosperms suggested that the shoot-specific expression of *WUS* and root-specific expression  
87 of *WOX5* is restricted to angiosperms. Only single homologues of *WUS/WOX5* were identified  
88 in three gymnosperms (*Pinus sylvestris*, *Ginkgo biloba*, and *Gnetum gnemon*), which were  
89 expressed in both the shoot and the root, suggesting that a single *WUS/WOX5* functional gene  
90 performs its role both in the shoot and root meristems [28]. Basing on these results, it was  
91 proposed the hypothesis that the last common ancestor of seed plants contained a single  
92 *WUS/WOX5* precursor gene, and *WUS* and *WOX5* probably arose as a consequence of a gene  
93 duplication event followed by a neofunctionalization that took place at the base of angiosperms.  
94 Recent studies in *P. abies* found differentiate *WUS* and *WOX5* genes in its genome. *PaWOX5*  
95 was preferentially in roots tips, but also in shoot tips. However, no *PaWUS* expression was  
96 detected in any of the plant parts studied. Based on that, it was proposed that both genes  
97 originated before the split between gymnosperms and angiosperms, but the functional  
98 specialization took place only in the angiosperms lineage [29].

99 In the present work, the analysis of the *WOX* gene family in the conifer maritime pine (*Pinus*  
100 *pinaster* Aiton) is presented. Fourteen *WOX* genes have been identified and the phylogenetic  
101 relationships of these genes compared to other known *WOX* genes in green alga, bryophyte,  
102 lycophyte, pteridophyte, gymnosperm, and angiosperm representative species have been

103 analysed. The phylogenetic analyses have identified three members of the ancient clade, five  
104 members in the intermediate clade, and six members in the WUS clade including five clear  
105 orthologues of the angiosperm WUS-clade genes and a new member, *PpWOXX*, with no  
106 homologues in angiosperms. Furthermore, the expression pattern for each of the 14 *WOX* genes  
107 was analysed in different developmental stages during somatic embryo development, and in  
108 different germination stages and tissues in seedlings from zygotic embryos. The detection of  
109 discrete *PpWUS* and *PpWOX5* transcripts for the first time in a gymnosperm and their  
110 differentiated expression patterns, which was thought to be exclusive from angiosperms, might  
111 indicate that these genes perform similar roles to those described for their *Arabidopsis*. These  
112 results suggest that the functional specialization might have taken place before the split between  
113 angiosperms and gymnosperms. The identification of *WOX* genes in *P. pinaster* provides new  
114 insights into the *WOX* family evolution in plants and will facilitate molecular studies to  
115 characterize the function of stem cells in gymnosperms.

## 117 2. MATERIALS AND METHODS

### 119 2.1. Identification and phylogenetic analysis of the *Pinus pinaster* *WOX* gene family

#### 120 2.1.1. Identification

121 The identification of the *WOX* gene family members in *P. pinaster* was carried out by  
122 combining PCR-based detection and the screening of *P. pinaster* transcriptome data obtained in  
123 the frame of the European projects ProCoGen [30] and SustainPine [31]. Genome data, when  
124 available, were used to identify exon-intron pattern.

125 *WUSCHEL* (*WUS*) sequences from different species were found through the search in the public  
126 databases GenBank (<http://www.ncbi.nlm.nih.gov/>), Dendrome (<http://dendrome.ucdavis.edu/>),  
127 and Congenie (<http://congenie.org/>). After determining conserved domains and motifs through  
128 ClustalW alignments, a fragment of the coding sequence was amplified using cDNA obtained  
129 from *P. pinaster* embryos as template. The full *WUS* mRNA sequence was obtained by Rapid  
130 Amplification of cDNA Ends (RACE) using the FirstChoice RLM-RACE Kit (Ambion,  
131 Applied Biosystems Inc., Foster City, CA, USA) according to the manufacturer's instructions.  
132 The TBLASTN and BLASTP algorithms [32], and HMM profile via HMMER  
133 (<http://hmmer.org/>) with default settings were used for the screening of *P. pinaster*  
134 transcriptome and proteome data searching for sequences containing the characteristic *WOX*  
135 homeodomain. The full-length cDNAs were cloned using CloneJET PCR Cloning Kit (Thermo  
136 Scientific, Waltham, MA, USA) and sequenced (at least three clones per band) at the Oviedo

137 University DNA Analysis Facility (Spain). *WOX* sequences obtained in *P. pinaster* were also  
138 used as queries to identify new *WOX* sequences in the genomes of *Pinus taeda* and *Picea abies*.

139

#### 140 2.1.2. Phylogenetic analysis

141 Sequences for *WOX* proteins from green alga (*Ostreococcus tauri*), moss (*Physcomitrella*  
142 *patens*), lycophyte (*Selaginella moellendorffii*), fern (*Ceratopteris richardii* and *Cyathea*  
143 *australis*), gymnosperm (*Ginkgo biloba*, *Gnetum gnemon*, *Picea abies*, *Pinus pinaster*, *Pinus*  
144 *sylvestris*, and *Pinus taeda*), and angiosperm (basal angiosperm: *Amborella trichopoda*,  
145 monocots: *Oryza sativa* and *Zea mays*, and dicots: *Arabidopsis thaliana*, *Populus euphratica*,  
146 *Populus trichocarpa* and *Vitis vinifera*) representatives were identified through the search in  
147 public databases (accession numbers for all sequences are listed in Supplementary Table S1).

148 Protein sequences were aligned using the MAFFT plug-in in Geneious (Biomatters Ltd., New  
149 Zealand) and edited manually. Non-conserved parts of the sequences were excluded from the  
150 analyses to reduce noise. The unrooted amino acid sequence similarity trees were generated  
151 using the Geneious software by the Neighbour-Joining method and the Jukes-Cantor genetic  
152 distance model. The green alga *OtWOX* sequence was used as outgroup for the trees.

153 Non-synonymous (Ka) and synonymous (Ks) nucleotide substitution rates for the *WOX* gene  
154 family in *P. pinaster* were also calculated using the Computational Biology Unit (CBU) Ka/Ks  
155 Calculation tool (<http://services.cbu.uib.no/tools/kaks>). The resulting phylogenetic tree was  
156 obtained by the parsimony method.

157

## 158 2.2. Characterization of the *Pinus pinaster WOX* gene family

159 To characterize the *WOX* gene family we carried out expression and localization studies in a  
160 comprehensive range of tissues and stages of development by mean of quantitative real-time  
161 PCR (RT-qPCR), laser capture microdissection (LCM) and RNA sequencing (RNA-Seq), and  
162 fluorescent *in situ* hybridization (FISH).

### 163 2.2.1. Quantitative real-time PCR (RT-qPCR)

164 Gene expression analysis was performed by RT-qPCR in a Bio-Rad CFX96 Real-Time PCR  
165 Detection System (Bio-Rad, Hercules, CA, USA). *P. pinaster* ubiquitin gene (Acc. AF461687)  
166 was used as endogenous reference gene [33-35]. Specific primers for each gene were designed  
167 with Primer3 software [36] following the parameters recommended by Udvardi et al. [37]  
168 (Primers used in this work are listed in Supplementary Table S2). Individual reactions were  
169 assembled in triplicate with 5 µl of Fast SYBR Green Master Mix (Applied Biosystems Inc.,  
170 Foster City, CA, USA), oligonucleotide primers (0.20 µM each) and 100 ng of cDNA in a final

171 volume of 10  $\mu$ l. The following protocol was used for amplification: 95 °C 20 s; 45 cycles of 95  
172 °C 3 s and 60 °C 30 s, with a final melting curve to assess for non-specific products. For this  
173 purpose, negative controls (no template) and RT- controls (non-retrotranscribed RNA) were also  
174 included, and PCR amplicons from selected wells were cloned and sequenced.

175

#### 176 2.2.1.1. *Plant material*

177 The *P. pinaster* embryogenic line P5LV4.1, which had been obtained and cryopreserved as  
178 described by Alvarez et al. [38, 39], was used to study the expression of the *WOX* genes during  
179 somatic embryogenesis. After thawing the cryopreserved tissues, proembryogenic masses  
180 (PEMs) were cultured on proliferation medium, which consisted on WV5 salts and vitamins  
181 (Duchefa, Haarlem, The Netherlands) [40], 1 g l<sup>-1</sup> casein hydrolysate, 2.2  $\mu$ M benzyladenine  
182 (BA), 4.5  $\mu$ M 2,4-dichlorophenoxyacetic acid (2,4-D), 30 g l<sup>-1</sup> sucrose, 4 g l<sup>-1</sup> Gelrite (Duchefa),  
183 and 0.5 g l<sup>-1</sup> L-glutamine (Duchefa). The pH was adjusted to 5.8 before autoclaving and the  
184 glutamine was filter-sterilized and added after autoclaving. Cultures were maintained at 23 °C  
185 in darkness and subcultured to fresh medium every three weeks.

186 To promote maturation PEMs were disaggregated and cultured onto a piece of sterile filter  
187 paper Whatman #2 70 mm diameter placed on maturation medium (150 mg per plate). This  
188 medium consisted on VW5 salts (Duchefa), 60 g l<sup>-1</sup> sucrose, and 9 g l<sup>-1</sup> Gelrite (Duchefa). The  
189 pH was adjusted to 5.8 before autoclaving. The medium was supplemented with 80  $\mu$ M abscisic  
190 acid (ABA) (Duchefa) and the amino acid mixture from embryo development medium (EDM)  
191 [41], which was composed of 525 mg l<sup>-1</sup> L-asparagine, 500 mg l<sup>-1</sup> L-glutamine, 175 mg l<sup>-1</sup> L-  
192 arginine, 19.75 mg l<sup>-1</sup> L-citrulline, 19 mg l<sup>-1</sup> L-ornithine, 13.75 mg l<sup>-1</sup> L-lysine, 10 mg l<sup>-1</sup> L-  
193 alanine, and 8.75 mg l<sup>-1</sup> L-proline. All amino acids were supplied by Duchefa, except L-  
194 citrulline (Alfa Aesar, Karlsruhe, Germany). Both ABA solution and EDM amino acid mixture  
195 were filter-sterilized and added after autoclaving. Cultures were maintained in darkness at 23 °C  
196 and subcultured to fresh medium every four weeks.

197 Material from four different developmental stages was collected along the maturation process  
198 (Figure 1A-D), based on the classification established by Hakman and von Arnold [42] and  
199 adapted by Tereso et al. [43]: proembryogenic masses proliferating in the presence of the plant  
200 growth regulators auxins and cytokinins (PEM); early embryos (EE), with a translucent embryo  
201 proper and a long suspensor; late embryos (LE), with a prominent and opaque embryo proper;  
202 and mature embryos (ME), which have well-defined apical meristem and cotyledons. Samples  
203 were immediately frozen in liquid nitrogen and stored at -80 °C until analysis was carried out.

204 *WOX* gene family expression dynamics were also analysed during seed germination and in  
205 different parts of three-week-old seedlings. For that purpose, mature seeds from open-pollinated

206 *P. pinaster* trees growing in a natural stand (ES08 Meseta Castellana provenance, Spain) and  
207 provided by ‘Servicio de Material Genético del Ministerio de Medio Ambiente’ (Spain) were  
208 imbibed in water with aeration for 48 hours, transferred to wet vermiculite and maintained at 23  
209 °C under a 16 h photoperiod.

210 As shown in Figure 1E-H, the analyses were carried out with germinated embryos with a radicle  
211 length inferior to 1 cm (G1), germinated embryos with a radicle between 1 and 2 cm (G2),  
212 germinated embryos with a radicle between 2 and 3 cm (G3), as well as in four different tissues  
213 from three-week-old seedlings: root tip (5 mm of the apical part of the root), shoot apex (3 mm  
214 of the emerging epicotyl including the shoot apical meristem and needle primordia), hypocotyl  
215 (a portion of 5 mm situated right under the shoot apex), and cotyledons. All tissues were  
216 immediately frozen in liquid nitrogen after isolation and stored at -80 °C until use.

217

#### 218 *2.2.1.2. RNA extraction and cDNA synthesis*

219 RNA was extracted using the GeneMATRIX Universal RNA Purification Kit (EURx, Gdańsk,  
220 Poland). The RNA was quantified spectrophotometrically (260 nm) and its integrity was checked  
221 by agarose gel electrophoresis. For each sample, one microgram of total RNA (0.5 µg for  
222 somatic embryogenesis samples) was reverse transcribed with the High Capacity cDNA  
223 Reverse Transcription Kit (Applied Biosystems Inc., Foster City, CA, USA) following the  
224 manufacturer’s instructions.

#### 225 *2.2.1.3. Data analysis*

226 Analysis of the RT-qPCR data was performed with the qpcR package for R software ([www.dr-  
227 spiess.de/qpcR.html](http://www.dr-spiess.de/qpcR.html)), which allows the fitting of the RT-qPCR fluorescence raw data to a five-  
228 parameter sigmoidal model for obtaining essential PCR parameters such as efficiency, threshold  
229 cycle and transcript abundance [44]. Relative abundance of each transcript was calculated as the  
230 mean of the three technical replicates and normalized to the expression value of the reference  
231 gene in each sample. Results are expressed as mean normalized expression values ± standard  
232 error of three biological replicates. Significant differences in mRNA levels were determined by  
233 t-test analysis or ANOVA using the Student–Newman–Keuls test for post hoc comparisons  
234 (SIGMA-PLOT v11 software, Chicago, IL, USA).

235

#### 236 *2.2.2. Laser Capture Microdissection (LCM) and RNA sequencing (RNA-Seq)*

237 To complement the information obtained by RT-qPCR and to gain insight into the expression  
238 pattern of the *WOX* gene family, different tissues of one-month-old seedlings were isolated by  
239 LCM and transcripts were studied by RNA-Seq.

240

241           2.2.2.1. *Plant material*

1  
2 242 *P. pinaster* seeds (Sierra de Oria provenance, Spain) were imbibed in water with aeration for 48  
3  
4 243 hours, transferred to wet vermiculite and maintained at 23 °C under a 16 h photoperiod.  
5 244 Fourteen days after imbibition, seedlings were individually transferred to a 0.2-l pot with soil  
6  
7 245 and watered twice a week with distilled water. The seedlings were harvested 1 month after the  
8  
9 246 emergence of the shoots over the vermiculite. The seedlings were cut and tissue sections of 5  
10 247 mm were mounted in a specimen holder with optimal cutting temperature (OCT) embedding  
11 248 medium (Tissue-Tek, USA) and snap-frozen in liquid nitrogen for cryostat sectioning. The  
12 249 frozen samples were stored at -80 °C until use.  
13  
14  
15  
16 250

17  
18 251           2.2.2.2. *Laser capture microdissection*

19  
20 252 The Laser Capture Microdissection (LCM) procedure was carried out as previously described in  
21 253 Cañas et al. [45]. Twenty-µm-thick sections were made using a cryostat (HM 525, Thermo,  
22 254 USA) at -20 °C and mounted on PET-membrane 1.4 µm steel frames (Leica Microsystems,  
23 255 Wetzla, Germany) with the help of a plexiglass Frame Support (Leica Microsystems, Wetzla,  
24 256 Germany). Before the microdissection, samples were fixed in cold 100% ethanol for 10 s, the  
25 257 OCT was removed in DEPC-treated water for 2 minutes and refixed in 100% ethanol for 1  
26 258 minute. Subsequently the samples were air-dried and used for microdissection. The  
27 259 microdissection was made in a laser microdissector (LMD700, Leica Microsystems, Wetzla,  
28 260 Germany). The microdissection samples were placed into the caps of 0.5 ml tubes containing 10  
29 261 µl lysis buffer from the RNAqueous-Micro RNA Isolation Kit (Ambion, USA). Before RNA  
30 262 extraction, all the samples were placed at -80 °C. All the RNA extractions were performed using  
31 263 the standard-volume protocol (non-LCM) with the RNAqueous-Micro RNA Isolation Kit  
32 264 (Ambion, USA).  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42

43 265 Samples from 14 different tissues were isolated by LCM: Apical Meristem (AM), Emerging  
44 266 Needles (EN), Young Needles Mesophyll (YNM), Young Needles Vascular (YNV), Cotyledon  
45 267 Mesophyll (CM), Cotyledon Vascular (CV), Hypocotyl Cortex (HC), Hypocotyl Vascular  
46 268 (HV), Hypocotyl Pith (HP), Root Cortex (RC), Root Vascular (RV), Developing Root Cortex  
47 269 (DRC), Developing Root Vascular (DRV) and Root Meristem (RM).  
48  
49  
50  
51  
52 270

53  
54 271           2.2.2.3. *cDNA amplification*

55  
56 272 As the amounts of RNA isolated from LCM samples were not enough for 454 pyrosequencing,  
57 273 a previous cDNA synthesis and amplification were made using the Conifer RNA Amplification  
58 274 (CRA+) protocol described in Cañas et al. [45].  
59  
60  
61  
62  
63  
64  
65

1 275 The quantity of the amplified ds cDNA was determined using the Quant-iT™ PicoGreen®  
2 276 dsDNA Kit (Invitrogen, Paisley, UK). The quality of the amplified ds cDNA was determined  
3 277 using the Agilent 7500 DNA Kit in the 2100 Bioanalyzer (Agilent, CA, USA).  
4

5 278

#### 7 279 2.2.2.4. 454 pyrosequencing

9 280 RNA-Seq was performed at the University of Málaga ultrasequencing facility using the GS-  
10 281 FLX+ platform with a GS FLX Titanium kit (Roche Applied Sciences, Indianapolis, IN, USA).  
11 282 Each sample was run in one half of a 454 PicoTiterPlate following the manufacturer's  
12 283 sequencing protocol.

13 284 The quantity of the cDNA libraries was determined using the Quant-iT™ PicoGreen® dsDNA  
14 285 Kit (Invitrogen, Paisley, UK). The quality of the cDNA libraries was determined using the  
15 286 Agilent High Sensitivity DNA Kit in the 2100 Bioanalyzer (Agilent, CA, USA). The runs were  
16 287 analysed using the Roche GS-FLX+ software. The high throughput sequencing data have been  
17 288 deposited in NCBI's Gene Expression Omnibus [46] and are accessible through GEO Series  
18 289 accession number GSE78263 (<http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE78263>).

#### 21 291 2.2.2.5. 454 pyrosequencing reads pre-processing, assembling and mapping

22 292 The raw data were first checked for quality using the *fastqc* software. Based on examination of  
23 293 the output quality plots it was decided to clip off the first 35 bp of each read using the FastX  
24 294 toolkit (*fastx\_trimmer*). Next, the reads were filtered for overall quality using  
25 295 *fastq\_quality\_filter* with a minimum Q-score of 30 and minimum remaining length of 60%. The  
26 296 remaining reads were subsequently used for read mapping with the BWA software (MEM  
27 297 option) [47] against the transcript sequences of the 14 *P. pinaster* *WOX* genes.  
28

29 298

#### 30 299 2.2.3. *Fluorescent in situ hybridization (FISH)*

31 300 The visualization of *PpWUS*, *PpWOXX* and *PpWOX3* gene expression domains in the shoot  
32 301 apex was carried out through mRNA fluorescent *in situ* hybridization (FISH). For that purpose,  
33 302 shoot apices inferior to 5 mm long were harvested from three-week-old seedlings obtained as  
34 303 mentioned in 2.2.1.1. Tissues were immediately fixed with freshly prepared FAA solution  
35 304 (3.7% formaldehyde, 5% glacial acetic acid, 50% ethanol) at 4 °C under vacuum overnight.  
36 305 Then, they were dehydrated in an ascendant ethanol series (50, 75, 90, and 100%) and  
37 306 maintained in 100% ethanol at 4 °C until next step.

38 307 Tissues were infiltrated and embedded with Technovit® 8100 (Heraeus kulzer GmbH,  
39 308 Wehrheim, Germany) according to manufacturer's instructions. Embedded shoot tips were

309 sectioned longitudinally in a microtome at 10  $\mu\text{m}$  thickness and sections were mounted on  
310 Menzel-Gläser Superfrost Ultra Plus slides (Thermo-Scientific, Waltham, Massachusetts, USA).  
311 Air-dried sections were directly used for *in situ* hybridization following the protocol described  
312 by Valledor et al. [48] with some modifications. Shoot apex sections were initially incubated in  
313 0.5% (v/v) Triton X-100 in PBS for 10 minutes and washed with PBS for 5 minutes.  
314 Subsequently, sections were treated with 2% (w/v) cellulase in PBS for 2 hours at room  
315 temperature and, after a wash step with PBS for 5 minutes, were also treated with HCl 0.2N for  
316 30 minutes. After a new wash step with PBS, sections were equilibrated with 2X SSC buffer for  
317 5 minutes and prehybridized with hybridization buffer HB50 (50% (v/v) formamide in 2X SSC  
318 + 50 mM phosphate buffer pH 7.0) for 2 hours at 37 °C. After denaturing samples at 78 °C for 5  
319 minutes, 8  $\mu\text{l}$  of hybridization mix were applied onto each section and maintained at 78 °C for 5  
320 minutes. Hybridization mix was composed by 20% (w/v) dextran sulfate, hybridization buffer  
321 HB50, and 100  $\mu\text{M}$  solution of the corresponding labelled probe in a proportion 2:1:1. Single-  
322 stranded antisense probes of 33 nucleotides long labelled with Cyanine 5 (Cy5) in their 3' end  
323 were designed to hybridize in a specific region of each mRNA (Probes are listed in  
324 Supplementary Table S2). Tissue sections were also incubated without any probe as a negative  
325 control, in order to evaluate the presence of autofluorescence. Then, sections were maintained  
326 overnight at 55 °C in a moist chamber.  
327 After hybridization, sections were washed with 2X SSC and 1X SSC at 40 °C for 15 and 10  
328 minutes, respectively. Subsequently, two additional wash steps with 0.5X SSC and autoclaved  
329 ddH<sub>2</sub>O for 10 and 2 minutes, respectively, were performed at room temperature. Sections were  
330 then incubated with 4,6-diamidino-2-phenylindole (DAPI; AppliChem GmbH, Darmstadt,  
331 Germany) 1  $\mu\text{g ml}^{-1}$  for 15 minutes. Finally, sections were washed with autoclaved ddH<sub>2</sub>O for 5  
332 minutes, air-dried and mounted with Mowiol<sup>®</sup> 4-88 (AppliChem GmbH, Darmstadt, Germany).  
333 Sections were observed and photographed with a Leica DMRXA fluorescence microscope  
334 (Leica Microsystems, Wetzlar, Germany) and images were processed with ConfocalUniovi  
335 ImageJ software (<http://spi03.sct.uniovi.es/confocaluniovi/>).

### 3. RESULTS

#### 3.1. Identification and phylogenetic analysis of the *Pinus pinaster* *WOX* gene family

340 The *P. pinaster* genome has been sequenced in the frame of the European project ProCoGen but  
341 a draft of the genome has not been released yet. We were able to identify 14 *WOX* genes in the  
342 *P. pinaster* genome by combining PCR-based detection and the screening of *P. pinaster*  
343 transcriptome data (SustainPine DB, <http://www.scbi.uma.es/sustainpinedb/>). All these genes  
344 showed the characteristic highly conserved HD and motifs of *WOX* genes. The gene structures  
345 of 11 out of 14 *WOX* genes were obtained by comparing the DNA and RNA sequences (Figure

2). We found clear orthologues for the *Arabidopsis* *WOX2*, *WOX3*, *WOX4*, *WOX5*, *WUS* and *WOX13* that were designated as *PpWOX2*, *PpWOX3*, *PpWOX4*, *PpWOX5*, *PpWUS*, and *PpWOX13*, respectively. The rest of *WOX* genes did not have clear orthologues with other angiosperm *WOX* genes and were named *PpWOXA*, *PpWOXB*, *PpWOXC*, *PpWOXD*, *PpWOXE*, *PpWOXF*, *PpWOXG*, and *PpWOXX*. Our screening also allowed the identification of 11 *WOX* genes in *P. taeda* (*PtWOX2*, *PtWOX3*, *PtWOX4*, *PtWOX5*, *PtWUS*, *PtWOXX*, *PtWOX13*, *PtWOXA*, *PtWOXB*, *PtWOXE* and *PtWOXG*) and two new *WOX* genes in *P. abies* (*PaWOXG* and *PaWOXX*). Accession numbers for all sequences identified in this work can be found in Supplementary Table S1.

Phylogenetically, *PpWOX* genes were distributed throughout the three clades established by van der Graaff et al. [4] (Figure 3). *PpWOX13*, *PpWOXA* and *PpWOXG* are members of the ancient clade, which includes *WOX* genes present in green algae and all land plants. *PpWOXB*, *PpWOXC*, *PpWOXD*, *PpWOXE* and *PpWOXF* belong to the intermediate clade. The *WUS* clade, originally defined as specific from seed plants, included the genes *PpWUS*, *PpWOX2*, *PpWOX3*, *PpWOX4*, *PpWOX5* and *PpWOXX* (Figure 4). *PpWOXX* is a new gene that had not been described in any other conifer species until this moment. A thoroughly screening in public databases allowed us to identify orthologues of this gene present in the genome of the conifers *P. abies* and *P. taeda*, but it was not found in any angiosperm species. The phylogenetic analysis showed that the *WOXX* pine orthologues constitute a monophyletic group that occupies the basal position of the *WUS* clade and group together with *G. gnemon* *GgWOXY* gene reported by Nardmann and Werr [49].

The analysis of the 14 *WOX* polypeptide sequences showed that all *P. pinaster* *WOX* proteins contained the characteristic *WOX* HD motif. All *WUS*-clade members contained the characteristic *WUS* box motif T-L-X-L-F-P. In addition, the EAR motif (L-X-L-X-L) is present in *PpWUS* and *PpWOX5* proteins after the HD and the *WUS* box (Figure 5A). Furthermore, similarly to *Arabidopsis* and other species, *PpWUS* deduced protein has a 66 amino acid homeodomain with a Y residue at position 21 that is absent in the rest of *PpWOX* proteins (Figure 5B).

Regarding substitution rates, all Ka/Ks values obtained for each node of the *P. pinaster* *WOX* phylogenetic tree were inferior to 1, which indicates that the evolution of this family in *P. pinaster* was under negative or purifying selection. That is, there was pressure to conserve protein sequences as changes in their sequence might cause a disruption of their function (Figure S1).

### 3.2. Characterization of the *Pinus pinaster* *WOX* gene family

In order to gain insight into the specific role of each *PpWOX* gene in plant development, their expression during somatic embryogenesis and seed germination was analysed by quantitative real time PCR (RT-qPCR). Transcripts from each isolated gene were detected at least in some of the stages or tissues included in this study, which indicated that they are not pseudogenes. Members of the ancient clade, *PpWOX13*, *PpWOXA* and *PpWOXG*, were shown to be constitutively expressed, and their expression was higher during embryogenesis (Figures 6 and 7). However, the intermediate-clade members *PpWOXB*, *PpWOXC*, *PpWOXD* and *PpWOXE* were expressed exclusively during embryogenesis, reaching a peak in the early embryo phase (Figure 6). Their levels were very low in the mature embryo and no expression was detected after the beginning of germination. *PpWOX2*, member of the WUS clade, showed a similar expression pattern. However, the expression of the last intermediate-clade member *PpWOXF* increased gradually during embryogenesis and reached its maximum level at the mature-embryo stage. During germination its levels dramatically decreased. No transcripts were detected in seedlings for *PpWOX2*, *PpWOXB*, *PpWOXC*, *PpWOXD*, *PpWOXE* and *PpWOXF* genes.

*PpWOXX*, *PpWUS* and *PpWOX5* showed a similar expression pattern during embryogenesis, as their expression reached their maximum at mature-embryo stage (Figure 6). However, in seedlings, while *PpWUS* expression was only detected in the shoot apex, *PpWOX5* transcripts were preferentially located in the root tip of seedlings, with low levels of expression in other seedling tissues (Figure 7). Similar to *PpWUS*, *PpWOX3* and *PpWOXX* expression was restricted to the shoot apex of seedlings, although transcripts from both genes were also found at a very low level in the hypocotyl (Figure 7).

*PpWOX4* expression levels were quite constant during embryogenesis and increased progressively during germination. In seedlings, this gene was mainly expressed in the hypocotyl. Lower levels were detected in the shoot apex and cotyledons, and very little expression was found in the root apex (Figures 6 and 7).

To gain insight into the expression pattern of the *WOX* gene family, different tissues of one-month-old seedlings were isolated by LCM and transcripts were studied by RNA-Seq. RNA-Seq results confirmed that only members of the ancient and WUS clades were expressed in seedlings. Members of the ancient clade (*PpWOX13*, *PpWOXA* and *PpWOXG*) were expressed in most tissues, while *PpWOX* members of the WUS clade had specific expression patterns suggesting a neofunctionalization phenomenon for these genes (Figure 8).

418 Fluorescent *in situ* hybridization (FISH) was performed in order to determine the precise  
419 expression domain of *PpWUS*, *PpWOXX* and *PpWOX3* genes in the shoot apex of three-week-  
420 old seedlings (Figure 9, Supplementary Figures S2 and S3). Both *PpWUS* and *PpWOXX* were  
421 shown to be expressed in a few cells located in the central region of the meristem. In particular,  
422 *PpWOXX* expression was detected in cells situated in the third cell layer (Figure 9C-D), whereas  
423 *PpWUS*-expressing cells were situated slightly deeper in the meristem (Figure 9A-B). On the  
424 other side, the gene *PpWOX3* was expressed in the peripheral zone of the meristem, where  
425 lateral organs initiate. Specifically, signal was detected in the putative founder cells of lateral  
426 organs, and in leaf primordia (Figure 9E-F).

427  
428 In order to complement all the information obtained in this work, we have summarized the data  
429 concerning the expression domains and putative functions of WOX proteins in the literature  
430 relative to angiosperms and gymnosperms in Table 1.

## 431 432 **4. DISCUSSION**

### 433 434 **4.1. Identification and phylogenetic analysis of the *Pinus pinaster* WOX gene family**

435 Increasing availability of data on the genome and transcriptome of several gymnosperms is  
436 facilitating the study of the evolution of their gene families [50] (Table 1). In this work, we  
437 report the identification of 14 WOX genes in *P. pinaster*, including three WOX genes not  
438 previously described in any other conifer species (*PpWOXA*, *PpWOXG* and *PpWOXX*). Our  
439 screening also allowed the identification of 11 WOX genes in *P. taeda* and two new WOX gene  
440 in *P. abies*. Recently, Hedman et al. [29] had characterized the WOX gene family in *P. abies*,  
441 which comprised a total of 11 WOX genes. In accordance with their results, our phylogenetic  
442 analyses showed that *PpWOX* genes are distributed along the three clades established in WOX  
443 phylogeny [4] supporting the hypothesis that a major diversification in WOX gene family took  
444 place before the split between angiosperms and gymnosperms.

445 Basing on phylogenetic analysis, it has been proposed that the WOX gene family has a  
446 monophyletic origin and that the last common ancestor of green algae and land plants contained  
447 at least one WOX member [51]. The ancient clade is present in all major plant lineages,  
448 including green algae, and lower plants only contain members from this clade. Basing on these  
449 observations, the ancient clade is thought to represent the oldest and most conserved clade of  
450 the WOX gene family [12, 52]. In *P. pinaster*, ancient clade includes three members, *PpWOX13*,  
451 *PpWOXA*, and *PpWOXG*. We found that these three genes are present in other *Pinus* species  
452 like *P. taeda*, while only *PpWOX13* and *PpWOXG* orthologues were detected in other  
453 gymnosperm genera like *Picea* and only *PpWOX13* orthologues in *Gnetum* or *Ginkgo*. These

1 454 ancient-clade genes appear to have a monophyletic origin and they might have arisen after  
2 455 duplication events that took place before the diversification of the *Pinus* genus, although this  
3 456 hypothesis should be confirmed in the future.

4 457 The intermediate clade, present in all vascular plants, and the WUS clade, exclusive from ferns,  
5 458 gymnosperms and angiosperms, originated subsequently by gene duplication and diversification  
6 459 from ancient members in the course of plant evolution [51, 53]. *WOX* gene family underwent a  
7 460 great expansion after the separation of mosses from other land plants, as the number of *WOX*  
8 461 genes increased substantially with the emergence of the vascular plant lineages [12, 54].  
9 462 Furthermore, modifications in the homeodomain 3D structure and the apparition of specific  
10 463 motifs in the protein sequence might have contributed to the functional change of *WOX* family  
11 464 during evolution [51].

12 465 Five *PpWOX* genes belong to the intermediate clade in *P. pinaster*. The phylogenetic analyses  
13 466 showed that these genes group very closely, which is consistent with the available data from  
14 467 other conifer species. This supports the hypothesis that there was a gene expansion of the  
15 468 intermediate clade within the *Pinaceae* family [29].

16 469 Phylogenetic analyses revealed that WUS-clade members emerged in the last common ancestor  
17 470 of leptosporangiate ferns and seed plants [55]. Whereas only one member has been reported in  
18 471 ferns [55], the WUS clade have expanded and evolved in seed plants. Similarly to that observed  
19 472 in *P. abies* [29], we found orthologues for most *Arabidopsis* WUS-clade members in *P. pinaster*  
20 473 except for *AtWOX1*, *AtWOX6* and *AtWOX7*. This suggests that *WOX2*, *WOX3*, *WOX4*, *WOX5*  
21 474 and *WUS* were present in the last common ancestor of angiosperms and gymnosperms, and a  
22 475 gene diversification happened after the bifurcation of both seed plant groups. Several members  
23 476 of the WUS clade have been involved in stem cell maintenance in the shoot meristem (*WUS*), in  
24 477 the root meristem (*WOX5*), in leaf marginal meristems (*WOX3*) and in vascular meristems  
25 478 (*WOX4*) in angiosperms [15, 18, 19, 56]. The fact that gymnosperms also contain orthologues  
26 479 for these genes could indicate that their functional specialization and association with discrete  
27 480 stem cell niches had been established prior to the divergence of gymnosperms and angiosperms,  
28 481 in concordance with the assumption made by Nardmann and Werr [49]. Recent interspecies  
29 482 complementation experiments have shown that gymnosperm WUS/*WOX5* proteins rescue  
30 483 *Arabidopsis wus-1* defects in both shoot apical stem-cell maintenance and flower organ  
31 484 formation [54]. This could suggest a conservation of their function all along seed plants,  
32 485 although more functional studies are needed in order to confirm this hypothesis.

33 486 Interestingly, a WUS-clade member, *PpWOXX*, not previously described in angiosperms was  
34 487 identified in *P. pinaster* in this work. We also identified orthologues of *PpWOXX* in the genome  
35 488 of other conifers such as *P. taeda* and *P. abies*. These sequences constitute a monophyletic  
36 489 group at the base of the WUS clade. A more detailed study of the HD peptide sequence showed  
37 490 that all the conifer *WOXX* proteins as well as the proteins GgWOXY, GgWOX2A and

491 GgWOX2B from the gymnosperm *Gnetum gnemon*, also included in the basal positions of the  
492 WUS clade, contain the particular sequence FYWF(QK)NR. The particular sequences  
493 FYWFQNR and FYWFQNH are characteristics of the intermediate- and WUS-clade WOX  
494 proteins, respectively [53, 55, 57]. This fact coupled to the recent identification of WUS-clade  
495 WOX members in the leptosporangiate ferns *Ceratopteris richardii* and *Cyathea australis*  
496 (*CrWUL* and *CaWUL*, respectively) [55] might indicate that, although these proteins are usually  
497 included in the WUS clade, they originated from a WOX gene present in the last common  
498 ancestor of all vascular plants, representing a transitional stage between intermediate- and  
499 WUS-clade proteins lost in the angiosperm lineage. Alternatively, they could have arisen as a  
500 consequence of a gene expansion in the gymnosperm lineage.

501

#### 502 **4.2. Characterization of the *Pinus pinaster* WOX gene family**

503 Available information about gene function in gymnosperms is limited, partly owing to the lack  
504 of a characterized mutant collection and the difficulty to carry out genetic transformation in  
505 many species. To characterize the WOX gene family in *P. pinaster* the expression pattern of  
506 each gene was analysed in different developmental stages and tissues by RT-qPCR and RNA-  
507 Seq. In addition, the gene expression of *PpWUS*, *PpWOXX* and *PpWOX3* in the shoot apex was  
508 analysed by FISH.

509 Transcripts of the ancient-clade members *PpWOX13*, *PpWOXA* and *PpWOXG* were detected in  
510 all the stages and tissues studied. In green algae and mosses, which only contain ancient-clade  
511 members, it was reported that the single WOX gene identified in *Ostreococcus tauri* participated  
512 in its maintenance in an undifferentiated state [12], whereas ancient-clade genes played an  
513 important role in stem cell formation and regeneration in *Physcomitrella patens* [58]. Previous  
514 reports in *Arabidopsis* [12, 59] and *P. abies* [29] showed that members of the ancient clade are  
515 expressed in most tissues and developmental stages and their function could be related to root  
516 initiation, embryo development, floral transition, and replum formation.

517 All the intermediate-clade members and the WUS-clade member *PpWOX2* were expressed  
518 during embryo development and no expression was detected once the embryos germinated. All  
519 these genes (except *PpWOXF*) are expressed mainly during the first stages of embryo  
520 development. This pattern is similar to that observed for *PaWOX8/9* and *PaWOX2* genes in *P.*  
521 *abies* [25, 26, 60]. *PaWOX8/9* RNA interference (RNAi) lines showed an altered orientation of  
522 the cell division planes at the basal part of embryonal masses during early embryo development,  
523 giving rise to aberrant embryos. *PaWOX2* RNAi affected the establishment of the border  
524 between the embryo proper and the suspensor. Besides, suspensor cells do not elongate as usual  
525 and the protoderm was not established properly. No effects were found when *PaWOX2*  
526 interference happened after late embryos were formed. The high homology and the similar  
527 expression pattern between *PpWOX2* and *PaWOX2* suggest that its function could be conserved

528 in conifers. Similarly, intermediate-clade genes *PpWOXB*, *PpWOXC*, *PpWOXD* and *PpWOXE*  
529 might be involved in apical-basal polarity establishment during early embryogenesis. Their  
530 orthologues in *Arabidopsis* *AtWOX8*, *AtWOX9* and *AtWOX2* are also involved in early  
531 embryonic pattern formation [13, 24]. The intermediate-clade gene *PpWOXF* showed a different  
532 expression pattern from other intermediate members. The highest transcript abundance was  
533 found in mature embryos, detecting very little expression during the initial stages of both  
534 embryogenesis and germination. According to the phylogenetic analyses, this gene is closely  
535 related to *WOX11* and *WOX12* genes from different angiosperm species. The expression and  
536 function of *AtWOX11* and *AtWOX12* has so far not been described in detail in *Arabidopsis* but  
537 recent studies showed that both genes are involved in *de novo* root organogenesis [61]. Based  
538 on the available information, the role of *PpWOXF* remains unknown and more studies will be  
539 needed to clarify its function.

540 Some members of the WUS clade are involved in stem-cell regulation. *PpWOX3* is homologue  
541 to *WOX3* genes from various angiosperm species [17, 62] and the conifer *P. abies* [27, 29]. In  
542 *Arabidopsis*, *AtWOX3/PRS* is expressed in embryos defining a border between the ad- and  
543 abaxial sides of the cotyledons [13, 63], and in lateral regions of young primordia [17]. Alvarez  
544 et al. [27] reported that *PaWOX3* has an important role in the lateral outgrowth of lateral organs  
545 in *P. abies* similar to the function of its angiosperm orthologues. By *in situ* hybridization, these  
546 authors also found *PaWOX3* expression in the lateral parts of the shoot meristem from adult  
547 vegetative buds during the shoot elongation period, but not during the dormant phase.  
548 Previously, it had been reported *WOX3* expression in the periphery of the SAM in other  
549 gymnosperm species such as *G. gnemon* and *P. sylvestris* [49]. In particular, *GgWOX3* initially  
550 presented a ring-shaped expression domain in the periphery of the SAM, being subsequently  
551 restricted to the leaflet precursors. *PsWOX3* was first detected in cells situated in the surface of  
552 the peripheral zone (PZ) of the SAM, where leaf initiation begins, and in the apical cells of leaf  
553 primordia. Expression of *PpWOX3* in *P. pinaster* was detected during embryo development and  
554 later preferentially in the shoot apex, being also slightly expressed in the emerging needles.  
555 Furthermore, analysis of its expression in the shoot apex by FISH showed that this gene is  
556 expressed in cells from the PZ of the meristem that will give rise to new lateral organs and in  
557 needle primordia. This expression pattern suggests a conserved function in expansion and  
558 development of lateral organs.

559 *PpWOX4* grouped together with other *WOX4* genes described in angiosperms and  
560 gymnosperms, constituting a monophyletic group. *WOX4* is transcribed in the developing  
561 vasculature of multiple tissues and was predominantly expressed in hypocotyls of *Solanum*  
562 *lycopersicum* [16]. Recent studies in *Arabidopsis* and *S. lycopersicum* showed that *WOX4* is  
563 closely related to vascular cambium promoting differentiation and/or maintenance of the  
564 vascular procambium, the initial cells of the developing vasculature. Our analysis showed that

565 *PpWOX4* expression increases during embryo germination and is higher in the hypocotyl than in  
566 other plant parts analysed. Transcripts of *PpWOX4* were detected specifically in the vascular  
567 tissue of hypocotyl and young needles by RNA-Seq analysis. This expression pattern could fit  
568 well with a function in the vascular procambium. However, we have not found functional  
569 studies of this gene in any gymnosperm species.

570 In *Arabidopsis*, the WUS-clade members *AtWUS* and *AtWOX5* are expressed in the organizing  
571 center (OC) of the SAM, and the quiescent center (QC) of the RAM, respectively. Both genes  
572 carry out a similar function maintaining a pool of undifferentiated cells in the SAM and RAM,  
573 respectively [14, 15]. In this work, we report the identification of orthologues for both *WOX5*  
574 and *WUS* in *P. pinaster* and *P. taeda*, which is in concordance with the results of Hedman et al.  
575 [29] in *P. abies*. However, whereas only *WOX5* transcripts were detected in conifers to date, one  
576 of the main breakthroughs of this work is the detection of discrete *PpWUS* and *PpWOX5*  
577 transcripts, suggesting that both genes are functional in *P. pinaster*. This is the first time that  
578 expression of both *WUS* and *WOX5* is detected in a gymnosperm species to our knowledge.  
579 *PpWOX5* is expressed during embryogenesis, especially in mature embryos, and preferentially  
580 in the seedling's root meristem. *PpWUS* is also expressed during embryogenesis, especially in  
581 mature embryos, and in the shoot apex of the seedlings. Furthermore, *PpWUS* expression was  
582 localized by FISH in the central zone (CZ) of the SAM. According to the model that describes  
583 the molecular basis of the SAM maintenance in angiosperms, WUS together with CLAVATA1  
584 (*CLV1*) and its ligand CLAVATA3 would form a regulatory loop that controls the balance  
585 between cell proliferation and differentiation in the SAM [3, 64]. Previous studies in our lab  
586 found a putative *CLV1* orthologue (*PpCLVIL*) that is overexpressed during *de novo* shoot  
587 organogenesis in *P. pinaster* [34]. These results suggest that at least some of the mechanisms  
588 involved in SAM homeostasis regulation might be conserved in both seed plant groups.  
589 However, a total comparison of these data is not possible due to the morphological differences,  
590 the different growth habits and the evolutionary distance between angiosperms and  
591 gymnosperms. While a zonation model of the SAM that divides the SAM into a CZ comprising  
592 stem cells and a surrounding PZ recruiting cells for differentiation has been claimed for all seed  
593 plants, a tunica-corpora model characteristic from most angiosperms cannot be applied to all  
594 gymnosperms. A recent study [65] showed that in most conifer species there is no a 'proper'  
595 tunica but a small number cells from the superficial layer situated in the summit of the SAM,  
596 which are designated apical initials, directly contribute to the superficial PZ and to the CZ. In  
597 *Pinus* genus, this central summit zone is composed by only three cells, which may have  
598 originated from the same initial cell. These cells divide anticlinally and perpendicular to each  
599 other giving rise to the surface cells from the PZ, and some of them (in some species, only one  
600 of the apical initials) also divide periclinally, giving rise to the stem cell population situated in  
601 the CZ. Despite the progress made in the understanding of the SAM architecture in conifers,

602 little information is available by the moment about the underlying molecular mechanisms of  
603 SAM formation and maintenance in these organisms. In summary, although the detection of  
604 discrete *WUS* and *WOX5* transcripts for the first time in a gymnosperm and their differentiated  
605 expression patterns might indicate that these genes perform similar roles to those described for  
606 their *Arabidopsis* orthologues, a deeper functional analysis of both genes is needed in order to  
607 validate this hypothesis. Interestingly, the expression domain of *PpWOXX*, the new WUS-clade  
608 member identified in conifers, during somatic embryogenesis and in the shoot apex is similar to  
609 that described for *PpWUS*. These results could indicate that this gene may play a role in the  
610 SAM maintenance. However, the information available at this moment is not enough to infer  
611 which the specific role of this gene is.

612  
613 In conclusion, our results suggest that an expansion of the intermediate clade took place within  
614 the *Pinaceae* family, that the last common ancestor of all seed plants contained a *WOX* gene  
615 representing a transitional stage between intermediate- and WUS-clade proteins, and that the  
616 last common ancestor of the extant gymnosperms and angiosperms contained both *WUS* and  
617 *WOX5* genes probably functionally specialized.

#### 618 619 **AUTHOR CONTRIBUTIONS**

620 The design of the study was made by JMA, RAC, CA, FMC and RJO and the experimental  
621 setup was planned by JMA, NB, RAC and RJO. JMA and NB performed most of the  
622 experimental work. JMA, RAC and NB analysed and interpreted the data. JMA drafted the  
623 manuscript. RAC, NB, CA, FMC and RJO revised the manuscript. All authors read and  
624 approved the final manuscript.

#### 625 626 **ACKNOWLEDGEMENTS**

627 This work was supported by the EU FP7 (ProCoGen 289841), INIA and FEDER cofunding  
628 (RTA2013-00048-C03-02), University of Oviedo (PAPI-17-PEMERG-3), a predoctoral grant  
629 from the ‘Plan de Ciencia Tecnología e Innovación del Principado de Asturias’, FICYT, Spain  
630 (BP10-098) to NB, and a grant from the ‘Spanish Ministerio de Economía y Competitividad’  
631 (BIO2015-73512-JIN; MINECO/AEI/FEDER, UE) to RAC. We thank Dr. Eduardo Cires for  
632 the helpful comments and Dr. Rubén Alvarez for critical reading of the manuscript.

2 865 Figure 1. Material used for quantitative real-time PCR (RT-qPCR) analysis of the *WOX* family  
3  
4 866 mRNA abundance in *Pinus pinaster* during the development of somatic embryos (A-D),  
5  
6 867 germination (E-G), and in different parts of young plants (H). (A) Proliferating proembryogenic  
7  
8 868 mass (PEM) in the presence of the plant growth regulators (PGRs) auxin and cytokinin; (B)  
9 869 early embryo (EE) 1 wk after withdrawal of PGRs; (C) late embryo (LE) before the emergence  
10 870 of cotyledons; (D) mature embryo (ME) after 12 wk on the maturation medium. (E) Germinated  
11 871 embryos with a radicle length inferior to 1 cm (G1); (F) germinated embryos with a radicle  
12 872 length between 1 and 2 cm (G2); (G) germinated embryos with a radicle length between 2 and 3  
13  
14 873 cm (G3). (H) Three-week-old seedling. Sa, shoot apex; Co, cotyledon; Hy, hypocotyl; Rt, root  
15  
16 874 tip. Note that the number of cotyledons in *P. pinaster* varies between 3 and 8. Bar, 1 mm (A-D);  
17  
18 875 1 cm (E-H).

19  
20 876  
21  
22 877 Figure 2. The *Pinus pinaster* *WOX* gene family. The structure of full-length (black line) cDNAs  
23  
24 878 is depicted. Exons (grey), when possible, were obtained by comparison between the cDNA and  
25  
26 879 genomic sequences; Conserved Homeodomain (red; HD). Open reading frames for *PpWOXD*,  
27  
28 880 *PpWOXF* and *PpWOXG* genes (yellow).

29 881  
30  
31 882 Figure 3. Phylogenetic tree of the *WOX* proteins. The tree contains sequences from green alga  
32 883 (*Ostreococcus tauri*, Ot), moss (*Physcomitrella patens*, Ph), lycophyte (*Selaginella*  
33 884 *moellendorffii*, Sm), fern (*Ceratopteris richardii*, Cr; and *Cyathea australis*, Ca), gymnosperm  
34 885 (*Ginkgo biloba*, Gb; *Gnetum gnemon*, Gg; *Picea abies*, Pa; *Pinus sylvestris*, Ps; *Pinus pinaster*,  
35  
36 886 Pp; and *Pinus taeda*, Pt), and angiosperm (basal angiosperm: *Amborella trichopoda*, Amt;  
37  
38 887 monocots: *Oryza sativa*, Os; and *Zea mays*, Zm; and dicots: *Arabidopsis thaliana*, At; *Populus*  
39 888 *euphratica*, Poe; *Populus trichocarpa*, Pot; and *Vitis vinifera*, Vv) representative species. The  
40  
41 889 unrooted amino acid sequence similarity trees were generated using the Geneious software by  
42  
43 890 the Neighbour-Joining method and the Jukes-Cantor genetic distance model. WUS clade (red;  
44  
45 891 W); intermediate clade (blue; I); ancient clade (black; A). The green alga OtWOX sequence was  
46  
47 892 used as outgroup for the tree (orange). *Pinus pinaster* sequences are highlighted with an  
48  
49 893 asterisk.

50 894  
51  
52 895 Figure 4. Phylogenetic tree of the WUS-clade *WOX* proteins. Species abbreviations are  
53 896 indicated as in Figure 3. The unrooted amino acid sequence similarity trees were generated  
54  
55 897 using the Geneious software by the Neighbour-Joining method and the Jukes-Cantor genetic  
56  
57 898 distance model. The green alga OtWOX sequence was used as outgroup for the tree. Each group  
58  
59  
60  
61  
62  
63  
64  
65

899 of orthologous genes is highlighted in a different colour. *Pinus pinaster* sequences are  
900 highlighted with an asterisk.

901

902 Figure 5. WOX protein domains. (A) Schematic representation of the conserved domains in all  
903 WOX family proteins in *Pinus pinaster*. Homeodomain (red; HD), WUS-box (orange; W), and  
904 EAR domain (purple). (B) Alignment of the 14 *P. pinaster* WOX homeodomain sequences.  
905 Note the extra Y residue in PpWUS sequence (red box).

906

907 Figure 6. Quantitative real-time PCR (RT-qPCR) analysis of the relative mRNA abundance of  
908 the *WOX* gene family in *Pinus pinaster* during embryo development and germination. PEM  
909 (proembryogenic mass); EE (early embryo); LE (late embryo); ME (mature embryo); G1, G2,  
910 and G3 (germinated embryo with radicle length <1 cm, 1-2 cm, and 2-3 cm, respectively).  
911 Different letters indicate significant differences in the relative mRNA abundance (Student–  
912 Newman–Keuls test,  $\alpha = 0.05$ ).

913

914 Figure 7. Quantitative real-time PCR (RT-qPCR) analysis of the relative mRNA abundance of  
915 the *WOX* gene family in different parts of three-week-old seedlings of *Pinus pinaster*. Root tip  
916 (Rt); Hypocotyl (Hy); Shoot apex (Sa); Cotyledon (Co). Different letters indicate significant  
917 differences in the relative mRNA abundance (Student–Newman–Keuls test,  $\alpha = 0.05$ ).

918

919 Figure 8. *PpWOX* gene expression obtained by RNA-Seq from tissues isolated through laser  
920 capture microdissection in one-month-old seedlings of *Pinus pinaster*. Apical Meristem (AM),  
921 Emerging Needles (EN), Young Needles Mesophyll (YNM), Young Needles Vascular (YNV),  
922 Cotyledon Mesophyll (CM), Cotyledon Vascular (CV), Hypocotyl Cortex (HC), Hypocotyl  
923 Vascular (HV), Hypocotyl Pith (HP), Root Cortex (RC), Root Vascular (RV), Developing Root  
924 Cortex (DRC), Developing Root Vascular (DRV) and Root Meristem (RM).

925

926 Figure 9. *PpWUS*, *PpWOXX* and *PpWOX3* transcript detection by fluorescent *in situ*  
927 hybridization (FISH) in longitudinal sections of shoot apex excised from three-week-old *Pinus*  
928 *pinaster* seedlings. Specific anti-mRNA probes labelled with Cyanine 5 (Cy5; red signal) were  
929 used. Blue signal represents nuclei staining with 4,6-diamidino-2-phenylindole (DAPI). (A)  
930 *PpWUS* transcripts were exclusively detected (arrows) in the central zone of the meristem. (B)  
931 Close up view. (C) Transcripts from *PpWOXX* also showed a restricted expression domain  
932 (arrows) in cells situated in the central zone of the meristem. (D) Close up view. (E) *PpWOX3*  
933 was shown to be expressed in the flanks of the meristem and in needle primordia. (F) Close up  
934 view. Needle primordia (np). Shoot apical meristem (sam) including the central zone (cz) and  
935 the peripheral zone (pz). All images were obtained with a Leica DMRXA fluorescence

936 microscope (Leica Microsystems, Wetzlar, Germany) and processed with ConfocalUniovi  
937 ImageJ software (<http://spi03.sct.uniovi.es/confocaluniovi/>). Bar, 50  $\mu$ m.

## **AUTHOR CONTRIBUTIONS**

The design of the study was made by JMA, RAC, CA, FMC and RJO and the experimental setup was planned by JMA, NB, RAC and RJO. JMA and NB performed most of the experimental work. JMA, RAC and NB analysed and interpreted the data. JMA drafted the manuscript. RAC, NB, CA, FMC and RJO revised the manuscript. All authors read and approved the final manuscript.

Table 1

Table 1. Summary of WOX protein expression domains and function. A comparison between angiosperms and gymnosperms. <sup>(\*)</sup> Genes described in this work.

Angiosperms					Gymnosperms			
Clade	Gene	Expression domain	Function	References	Orthologue	Expression domain	Function	References
WUS	<i>WUS</i>	SAM, floral meristem, ovule, anther	Stem-cell maintenance, anther and ovule development	[6, 14, 56, 66-68]	<i>PpWUS</i> <sup>(*)</sup> , <i>GbWUS</i> , <i>GgWUS</i>	Embryo, shoot tip	Unknown	[28]
	<i>WOX1</i>	Lateral organ primordia	Lateral organ formation	[13, 23, 69, 70]				
	<i>WOX2</i>	Apical embryo domain	Embryo patterning	[13, 24, 71]	<i>PpWOX2</i> <sup>(*)</sup> , <i>PaWOX2</i>	Embryo, Apical embryo domain	Embryo patterning	[26, 60, 72]
	<i>WOX3</i> ( <i>PRSI</i> , <i>NS1</i> , <i>NS2</i> )	SAM, peripheral zone	Promotes cell proliferation, lateral organ formation	[13, 17, 23, 70]	<i>PpWOX3</i> <sup>(*)</sup> , <i>PaWOX3</i> , <i>GgWOX3</i> , <i>GbWOX3A</i> , <i>GbWOX3B</i> , <i>PsWOX3</i>	Embryo, SAM, peripheral zone, cotyledons, needles	Lateral organ outgrowth	[27, 49]
	<i>WOX4</i>	Vascular cambium	Procambial development	[16, 73, 74]	<i>PpWOX4</i> <sup>(*)</sup> , <i>PaWOX4</i> , <i>GgWOX4</i> , <i>GbWOX4</i>	Germinating embryo, Vascular cambium	Unknown	[29, 49]
	<i>WOX5</i>	RAM	Stem-cell maintenance	[13, 15]	<i>PpWOX5</i> <sup>(*)</sup> , <i>PaWOX5</i> , <i>PsWOX5</i>	Embryo, RAM, SAM	Unknown	[28, 29]
	<i>WOX6</i> ( <i>PFS2</i> , <i>hos9</i> )	Female gametophyte	Prevents differentiation, cold-stress response	[75]				
	<i>WOX7</i>	Root	Lateral root development	[76]				
					<i>PpWOXX</i> <sup>(*)</sup>	Embryo, SAM, needles	Unknown	

Intermediate	<b>WOX8</b> ( <i>STPL</i> )	Basal embryo domain	Embryo patterning	[13, 24, 71]	<b><i>PpWOXB</i><sup>(*)</sup>, <i>PpWOXC</i><sup>(*)</sup>, <i>PpWOXD</i><sup>(*)</sup>, <i>PpWOXE</i><sup>(*)</sup>, <i>PaWOX8A</i>, <i>PaWOX8/9</i></b>	Basal embryo domain	Embryo patterning	[25, 60]
	<b>WOX9</b> ( <i>STIMPY</i> )	Basal embryo domain	Embryo patterning, promote cell proliferation	[13, 71]				
	<b>WOX11</b>	Root	Adventitious root formation	[61]	<b><i>PpWOXF</i><sup>(*)</sup>, <i>PaWOX8B</i>, <i>PaWOX8C</i>, <i>PaWOX8D</i></b>	Embryo	Unknown	[29]
	<b>WOX12</b>	Root	<i>De novo</i> root organogenesis	[77]				
Ancient	<b>WOX10</b>	Unknown	Unknown					
	<b>WOX13</b>	Root, inflorescence	Floral transition, root development	[12, 59]	<b><i>PpWOX13</i><sup>(*)</sup>, <i>PpWOXA</i><sup>(*)</sup>, <i>PpWOXG</i><sup>(*)</sup>, <i>PaWOX13</i></b>	All studied tissues	Unknown	[29]
	<b>WOX14</b>	Root, inflorescence	Floral transition, root development	[12]
