**Just Accepted**

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

# Intermetallic Co<sub>2</sub>FeIn Heusler Alloy Nanowires for Spintronics Applications

2  
3 ABSTRACT  
4  
5  
6

7 Cylindrical  $\text{Co}_2\text{FeIn}$  Heusler alloy nanowires are synthesized via template-assisted  
8 electrochemical deposition into the hexagonally self-ordered nanopores of hard-anodic alumina  
9 membranes. The electroplated nanowires, with  $180 \pm 20$  nm in diameter and around  $14.5 \mu\text{m}$  in  
10 length, exhibit a polycrystalline nature and they are homogenous in composition. High-resolution  
11 transmission electron microscopy (HR-TEM), selected area electron diffraction (SAED) and X-  
12 ray diffraction (XRD) analysis confirmed a cubic  $A2$  disordered phase of the ferromagnetic  
13 Heusler compound, with a lattice parameter of  $a = 5.764 \pm 0.001 \text{ \AA}$ . In addition, these structural  
14 characterizations reveal that the  $\text{Co}_2\text{FeIn}$  nanowires display a polycrystalline structure with a  
15 pronounced  $\{220\}$  texture. The temperature dependent magnetization behavior and anisotropy  
16 field distribution calculations display a dominant role of shape, magnetocrystalline and  
17 magnetoelastic terms on the effective magnetic anisotropy of  $\text{Co}_2\text{FeIn}$  alloyed nanowire arrays.  
18 Magneto-optical Kerr effect measurements performed on single freestanding nanowires, after  
19 releasing from the hosting alumina templates, confirmed competing behavior between shape and  
20 magnetocrystalline anisotropy contributions, which lead to complex magnetization reversal  
21 process. This fabrication technique offers a promising and new forward-looking synthesis of novel  
22 Heusler nanomaterials for spintronics applications.

## 1. Introduction

Nowadays there is an increasing interest for searching novel magnetic nano-materials with a high spin polarization at the Fermi energy, which are interesting for spintronics applications in magnetic data storage, like magnetic hard discs and random access memories (MRAMs), or magnetic domain wall race-track memory devices [1-4].

Heusler alloys are well-known suitable candidates for many applications, due to their tunable electronic structure, which influences their peculiar physical properties ranging from superconductivity [5], through semiconductivity [6], even to half-metallic ferromagnetism [7]. Half-metallicity is characterized by a metallic behavior in the majority spin channel and a semiconducting behavior with a gap at the Fermi level in the minority spin channel, which provides a 100% spin polarization [8]. Therefore, the half-metallic character of some Heusler alloys have attracted great interest due to their potential application as a highly spin-polarized current source in the research fields of thermoelectric [9], and spintronic devices [10-13].

Heusler alloys are ternary compounds with chemical formula  $X_2YZ$  showing various structures ranging from ordered  $L2_1$ , moderately ordered  $B2$  (Y-Z disorder), to completely disordered  $A2$  (X-Y-Z disorder) structural types. The X and Y atoms are usually selected from either transition or rare-earth metals, while the Z sub-lattice is represented by p-block element [8]. Heusler alloys are usually prepared as single or polycrystalline bulk materials or thin films [14-16]. Currently this fascinating group of materials faces a new challenge because of the downsizing to the nanoscale regime for numerous potential applications such as in spintronics, topological insulators and magnetic skyrmions [17].

1  
2  
3 The research on nanostructures is strongly motivated by the observation that points to the fact  
4 that the bulk material properties can abruptly change by scaling the material size down to the  
5 nanoscale dimension [18, 19]. This approach may enhance the typical properties of Heusler alloys  
6 usually exhibited in the form of bulk and offers the opportunity to incorporate these novel  
7 nanoscale materials into the products of industrial technologies, such as in data storage and  
8 thermoelectric cooling devices, among many other applications [20-24].  
9

10  
11  
12 The large interest on the fabrication of metallic and magnetic nanowires for many kinds of  
13 applications resulted in the revelation of novel binary or ternary Co-based alloy nanowires, such  
14 as Co-Ni [25-27], or Co-Cu [28, 29], Co-Fe-Ni [30] and Co-Fe-Cu [31] prepared by  
15 electrochemical deposition into the self-ordered nanopores of the anodic aluminum oxide (AAO)  
16 membranes. The peculiar one-dimensional (1D) geometry of the electrodeposited ferromagnetic  
17 nanowires has been recently reported to exhibit novel structural and physic-chemical features [32-  
18 35].  
19

20  
21  
22 Co<sub>2</sub>-based Heusler alloys have a peculiar role in the potential applications of spintronics based  
23 on their theoretically predicted half-metallic nature at the Fermi energy (100% spin polarization),  
24 high Curie temperature and small Gilbert damping [36]. However, up to now there are only few  
25 reports in the literature dealing with ternary intermetallic Co-based Heusler alloys nanowires: such  
26 as single crystal nanowires made of CoSiGe alloys grown by spontaneous chemical vapor transport  
27 displaying orthorhombic Co<sub>2</sub>Si structure [37]; Co<sub>2</sub>FeAl prepared by electrospinning with a wide  
28 range of thickness from 50 to 500 nm and having *B2* or *A2* disordered crystalline structure [38];  
29 polycrystalline fcc CoNiGa nanowires array potentiostatically electrodeposited into AAO  
30 templates [39]; electron-beam evaporated CoFeAl nanowires exhibiting highly efficient spin  
31 current induced by thermal-gradient spin injection [40]; Co<sub>2</sub>FeGa nanowires prepared by silica

2  
3 template assisted method exhibiting a highly ordered  $L2_1$  crystalline structure, and with an  
4 additional nonmagnetic  $\text{Co}_x\text{Fe}_{3-x}\text{O}_4$  surface layer of about 10 nm [41]; half-metal  $\text{CoH}_3$  1D  
5 molecular nanowires exhibiting ferromagnetic ground state induced by carrier doping with a  
6 theoretically predicted 100% spin-polarized current [42]; and more recently,  $\text{Fe}_2\text{CoSn}$  [43] and  
7  $\text{Co}_2\text{Mn}_{0.5}\text{Fe}_{0.5}\text{Sn}$  [44] nanowires showing a  $L2_1$  crystal structure (with an  $A2$  and/or  $B2$  type  
8 disorder), which were synthesized by template-based ac electrodeposition; among other nanowire  
9 shape Heusler based alloys [45, 46].

10  
11  
12 Since  $\text{Co}_2\text{FeIn}$  Heusler alloy was also predicted to exhibit a half-metallic nature [47], and it has  
13 also been earlier shown that the deposition of both Co-Fe and Co-In alloys from aqueous solutions  
14 is allowable [48, 49], we have synthesized Heusler-based  $\text{Co}_2\text{FeIn}$  alloy nanowires via template-  
15 assisted electrochemical deposition in the pores of AAO membranes. This easy and low-cost  
16 fabrication method opens up to the new possibility in the synthesis of novel Heusler nanomaterials  
17 suitable for spintronic applications.

39  
40 The fabrication procedure here employed is based on the template-assisted pulsed  
41 electrodeposition method, as schematized in Figure S1 a) to S1 c), by employing highly ordered  
42 nanoporous AAO membranes obtained through hard anodization (HA) method in oxalic acid  
43 electrolyte, as previously reported elsewhere [50-52]. Additional details on the synthesis of H-  
44 AAO and their use as templates are given in the Supporting Information.

**Figure 1:** (a) SEM micrograph of the hexagonally self-ordered nanopores of the H-AAO membrane, which was employed afterwards as a template for DC deposition of  $\text{Co}_2\text{FeIn}$  alloyed nanowires inside, and (b) the corresponding SEM cross-section image for the gold-capped  $\text{Co}_2\text{FeIn}$  nanowires array. The inset shows a higher magnification of the SEM cross-section image of nanowires array.

In the scanning electron microscopy (SEM) top-view image of Figure 1 a), it is shown the hexagonally self-ordered nanoporous hard-anodic aluminum oxide (H-AAO) membrane, where a mean nanopore diameter of about 180 nm and interpores distance around 300 nm can be respectively measured.

## 2.1 $\text{SiO}_2$ cover layer by atomic layer deposition

The prepared H-AAO membranes were coated by atomic layer deposition (ALD) technique with a protective  $\text{SiO}_2$  layer of 5 nm in thickness, as schematically depicted in Figures S1 b) and 1 c), to protect the further deposited metallic nanowires against corrosion and chemical etching [25, 27, 53]. The  $\text{SiO}_2$  cover layer was deposited into the pores of the H-AAO membranes by ALD working at 150°C from aminopropyltriethoxysilane (100°C), water (RT), and ozone (RT), which

1  
2  
3 were employed as precursors and oxidant agent, respectively [25-27, 53]. The ALD processes were  
4 performed in a Savannah 100 reactor (Cambridge Nanotech), employing long exposure times (45  
5 s) of the H-AAO membranes to the ALD precursors, followed by extended purge steps (90 s).  
6 High Purity Ar (99.999 %), with a flow of 50 sccm was employed as carrier and evacuation gas  
7 throughout the depositions.

## 14 15 **2.2 Electrodeposition of Co<sub>2</sub>FeIn alloyed nanowire arrays**

16  
17  
18  
19 Co<sub>2</sub>FeIn alloyed nanowires were grown into the nanopores of H-AAO membranes from aqueous  
20 electrolytes of Co, Fe and In salts, as well as a mixture of additives comprising boric and ascorbic  
21 acids, sodium chloride, saccharin and gelatin, respectively. For the electrodeposition process of  
22 Co<sub>2</sub>FeIn alloy nanowires inside the pores of the H-AAO template, it consisted firstly of the  
23 backside coating of one side of the SiO<sub>2</sub> functionalized H-AAO membranes with a gold layer by  
24 means of sputtering (Polaron SC 7620), which served as working electrodes in further  
25 electrodeposition steps (see Figure S1 b)). The potentiostatic Au electrodeposition made from a  
26 commercial gold plating solution (Orosene 999), gives rise to the growing of gold nanocontacts  
27 with length of about 2 μm, as shown in Figure 1b), Figure S1b), and Figure S3 a) of Supporting  
28 Info. After that, the Co<sub>2</sub>FeIn nanowires were electrochemically grown starting from an aqueous  
29 electrolytic bath containing: 0.198 M CoCl<sub>2</sub>, 0.072 M FeSO<sub>4</sub>, 0.023 M In<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, 0.243 M H<sub>3</sub>BO<sub>3</sub>,  
30 1.49 M NaCl, by adding a mixture of additives like ascorbic acid (5 mg/l), gelatine (2.5 mg/l) and  
31 saccharin (5 mg/l). A galvanostatic pulsed electrodeposition (PED) approach was followed for the  
32 synthesis of Co<sub>2</sub>FeIn Heusler alloy nanowires, as indicated in Figure S2 of the Supporting  
33 Information. The PED process was carried out in a common two-electrode electrochemical cell  
34 made of Teflon, with Pt serving as the counter electrode and the gold-coated H-AAO template as  
35 the working electrode, and performed at room temperature (RT), with a deposition pulse of 12 mA

3 for 1 s and a resting pulse at 0 mA (open circuit potential) for 1 s. The number of deposition pulses  
4 was adjusted in order to grow the Co<sub>2</sub>FeIn nanowires of about 15 μm in length. Afterwards, gold  
5 caps about 1.6 μm long were deposited in the upper part of the Co<sub>2</sub>FeIn nanowires, as a protection  
6 against corrosion in further chemical etching steps, as schematized in Figure S1 c), and can be  
7 clearly distinguished in the scanning electron micrograph of Figure 1 b).

### 14 15 **2.3 Experimental characterization of Co<sub>2</sub>FeIn alloy nanowires**

16  
17  
18  
19 Linear sweep voltammetry (LSV) technique was used to obtain polarization curves (I-V), by  
20 employing a potentiostat-galvanostat Amel 7050 measured in a three-electrode configuration with  
21 an Ag/AgCl reference electrode, and a Pt wire as the working electrode. The potentials were  
22 scanned in the range from 0.5 to -2.0 V, in negative direction, and afterwards reversed to the  
23 starting potential (0.5 V), at the three different sweeping rates of 20, 50 and 100 mV/s.  
24  
25  
26  
27  
28  
29  
30

31  
32 Structural characterization of the overall crystalline structure of Co<sub>2</sub>FeIn nanowire arrays grown  
33 in the H-AAO templates was determined by X-ray diffraction (XRD) analysis measured with a  
34 PANalytical X'Pert Pro MPD diffractometer employing Cu K<sub>α</sub> radiation ( $\lambda = 1.5418 \text{ \AA}$ ). The  
35 morphology and microstructure of the nanowires were respectively checked by using a scanning  
36 electron microscope (SEM), JEOL-6100 operated and 20 kV, and a transmission electron  
37 microscope (TEM), FEI-TITAN 80-300 kV operated at 300 kV. By employing the scanning  
38 transmission electron microscopy (STEM) mode, energy dispersive spectrometry (EDS) mapping  
39 images were obtained to take information on the distribution of chemical elements within  
40 individual nanowires. In order to perform the TEM analysis for the microstructural  
41 characterization of individual nanowires, they were released from the alumina membrane by  
42 chemical etching after dissolving it in a mixture of H<sub>3</sub>PO<sub>4</sub> (6 wt.%) and CrO<sub>3</sub> (1.8 wt.%) at 45 °C  
43

57  
58  
59  
60

1  
2  
3 for 48 h. The Co<sub>2</sub>FeIn nanowires coated with SiO<sub>2</sub> layer and covered with gold caps at both ends  
4  
5 were then filtered and suspended in an absolute ethanol solvent. Subsequently, a small amount of  
6  
7 nanowires was dispersed in ethanol-distilled water mixture (1:1) and sonicated for 30 min at RT.  
8  
9 Finally, the released nanowires with the protective coating were dropped in a Lacey carbon grid,  
10  
11 which was dried for 30 min under ambient environment for evaporating the solvent.  
12  
13  
14

15  
16 Thermomagnetic measurements and hysteresis loops (both, in parallel and perpendicular  
17  
18 direction with respect to the nanowires axis), were measured in the arrays of nanowires by using a  
19  
20 superconducting quantum interference device (SQUID), and Quantum Design magnetic property  
21  
22 measurement system (MPMS) technique, within the temperature range from 10 to 400 K, under  
23  
24 applied magnetic fields up to 50 kOe.  
25  
26  
27

28  
29 The magnetic behavior of single nanowires was also measured by magneto-optical Kerr effect  
30  
31 (MOKE) microscope in a NanoMOKE3 device (Durham Magneto-Optics) under applied AC fields  
32  
33 of 500 Oe at a frequency of 2.1 Hz. For that purpose, the nanowires were dropped into  
34  
35 monocrystalline Si wafers after releasing them from the nanoporous alumina template by wet-  
36  
37 chemical etching and suspended in ethanol, and then individually located by employing the laser  
38  
39 scanning microscopy option of the NanoMOKE3. The single isolated Co<sub>2</sub>FeIn nanowires were  
40  
41 carefully aligned with the direction of the applied magnetic field and measured employing  
42  
43 longitudinal MOKE configuration. Averaging of up to 200 cycles was performed in order to  
44  
45 improve the signal to noise ratio. Over 50 different nanowires were measured and the hysteresis  
46  
47 loops were analyzed in order to extract the switching field distribution.  
48  
49  
50  
51

### 52 **3. Results and discussions**

53  
54

#### 55 **3.1 Cyclic voltammetry of electrodeposited Co<sub>2</sub>FeIn Heusler alloy**

56  
57  
58  
59  
60

1  
2  
3 The electrochemical features of the Co-Fe-In alloy electrodeposition behavior in the presence of  
4 additives were investigated by linear sweep voltammetry, LSV, by measuring the current-voltage  
5 (I-V) curves. Figure 2 shows the cathodic parts of cyclic voltammograms obtained for deposition  
6 of individual elements of Co, Fe, In and Co-Fe-In alloy on a Pt wire electrode, measured employing  
7 an Ag/AgCl reference electrode. All electrolytes contained the same mixture of additives (0.243  
8 M  $\text{H}_3\text{BO}_3$ , 1.49 M NaCl, ascorbic acid, gelatine and saccharin). The cyclic voltammetry for a  
9 solution containing 0.198 M  $\text{CoCl}_2$  shows a single cathodic peak with the maximum at -0.83 V,  
10 which corresponds to the reduction of  $\text{Co}^{2+}$  into cobalt metal (see inset of Figure 2). This process  
11 was subsequently followed by the reduction of  $\text{H}^+$  leading to  $\text{H}_2$  evolution, which is also present  
12 in the same range of voltage for the supporting electrolyte containing no metal salts (labelled as  
13 Additives in Figure 2).  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28

29 The voltammetric curve for the aqueous solution containing 0.072 M  $\text{FeSO}_4$  indicates the  
30 reduction of  $\text{Fe}^{2+}$  by a broad peak starting at -0.9 V, which gradually passes to the hydrogen ion  
31 reduction reaction. Similarly, as in the case of Co the cyclic voltammetry curve corresponding to  
32 the deposition of In from the aqueous solution containing 0.023 M  $\text{In}_2(\text{SO}_4)_3$  shows a well-defined  
33 anodic peak with the maximum at -0.81 V. Nevertheless, iron and indium could also be inductively  
34 codeposited with Co(II) ions, in both, simple salt or complexed aqueous electrochemical baths [48,  
35 49, 54-55]. The initial abrupt current drop as the potential decreases is due to concentration  
36 depletion of metallic ( $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{In}^{3+}$ ) ions near the electrode surface. Subsequently, the current  
37 slowly reaches a stable plateau. Noteworthy, for Co and In baths the diffusion-controlled  
38 mechanism reaches its limit current density at lower potential values than for the Co-Fe-In  
39 electrolyte. Therefore, the addition of Fe together with rest of additives causes essential changes  
40 in electrolyte solution, which ultimately might affect the characteristics of the reduction process.  
41

58  
59  
60

**Figure 2:** Cyclic voltammogram of the supporting electrolyte (labelled as additives), as well as the electrolytes containing individual elements (Co, Fe and In) and mixed Co-Fe-In electrolyte. The inset shows a detail of the potentials range at which appear the deposition peaks of Co, Fe and In, together with the corresponding one of the respective Co-Fe-In alloy.

In the case of the Co-Fe-In alloy, the electrodeposition starts at -0.77 V and results in a single cathodic peak with maximum at -0.98 V. It is clear, that the co-deposition of the Co-Fe-In alloy takes place in the same range of voltage as for the deposition of individual elements. Therefore, this electrolyte is especially suitable for the electrochemical deposition of a ternary  $\text{Co}_2\text{FeIn}$  Heusler alloy.

### 3.2 Morphological, compositional and microstructural analysis of $\text{Co}_2\text{FeIn}$ nanowires

Figure 1 b) corresponds to a typical SEM cross-section view of the as-deposited densely packed array of  $\text{Co}_2\text{FeIn}$  alloyed nanowires inside the pores of the H-AAO template. Additional bottom

1  
2  
3 and top protective Au caps can also be well distinguished due to the back-scattered electrons (BSE)  
4 contrast. The resulting electroplated nanowire arrays have an averaged diameter of  $180 \pm 20$  nm,  
5 around 300 nm of interspacing distance and 14.5  $\mu\text{m}$  in length, with a  $\text{Co}_{48}\text{Fe}_{25}\text{In}_{27}$  averaged  
6 composition obtained from EDS analysis with the SEM, (see Figure S3 from Supporting Info).  
7  
8  
9

10  
11  
12  
13 STEM mode images and EDS elemental mapping of the single isolated nanowires after releasing  
14 them from the nanoporous H-AAO template have been taken in order to verify the shape and  
15 composition homogeneity of the  $\text{Co}_2\text{FeIn}$  alloyed nanowires grown by pulsed electrodeposition,  
16 as they are shown in Figure 3.  
17  
18  
19  
20  
21  
22

23  
24 These micrographs reveal that the Co, Fe and In chemical content distributions are very uniform  
25 along the entire nanowires. The protective  $\text{SiO}_2$  coating layer that covers the  $\text{Co}_2\text{FeIn}$  nanowires  
26 is rather uniform, as it can be clearly distinguished in the upper end of nanowire shown in the  
27 Figure 3 a). Local EDS analyses with TEM indicate an averaged percentage in atomic composition  
28 (at%) of  $\text{Co} = 47 \pm 1$ ,  $\text{Fe} = 25 \pm 1$ ,  $\text{In} = 28 \pm 1$ , for the Co-Fe-In alloyed nanowires, in good  
29 agreement with the EDS analysis carried out by SEM. Individual  $\text{Co}_2\text{FeIn}$  nanowires released from  
30 the hosting H-AAO membrane can be clearly distinguished from the low-magnification TEM  
31 image shown in the Figure S4 a) of Supporting Info, confirming the average nanowire diameter  
32 and length previously checked in the SEM images.

**Figure 3:** STEM image (a) and EDS elemental mapping analysis (b-d) of a single nanowire revealing that Co, Fe and In elements are uniformly distributed throughout the whole nanowire dimension. The scale shown in (a) applies also to figures (b-d).

High-magnification TEM image shown in Figure S4 b) of Supporting Info, disclose the rather uniform conformal SiO<sub>2</sub> coating layer deposited by ALD that covers the Co<sub>2</sub>FeIn alloyed nanowires, with a thickness of around 6 nm.

Microstructural analysis of single isolated Co<sub>2</sub>FeIn Heusler nanowires was performed by high-resolution transmission electron microscopy (HR-TEM) mode, as reported in Figure 4 a). The HR-TEM images, combined with electron diffraction experiments shown in Figure 4 b), reveal the

1  
2  
3 polycrystalline features of electrodeposited nanowires. In the HR-TEM analysis shown in Figure  
4 a), the polycrystalline structure of the nanowires is disclosed by direct observation of nanograins  
5  
6 into the same nanowire. However, they tend to display the {220} planes nearly oriented  
7  
8 perpendicular to the nanowire long axis exhibiting a pronounced {220} texture. The selected area  
9  
10 electron diffraction, SAED, patterns (Figure 4 b) show spotted rings that can be indexed to the  
11  
12 reflections of the (220), (400), (422), (440), (620), (444), (642), (660), (840) and (862) planes of a  
13  
14  $\text{Co}_2\text{FeIn}$  Heusler phase with a lattice parameter of  $a = 5.72 \pm 0.03 \text{ \AA}$ , which is lower than the  
15  
16 calculated equilibrium lattice constant reported in reference [47]. All of such reflections satisfy the  
17  
18 condition  $h + k + l = 4n$  (where  $n$  is an integer) with  $h$ ,  $k$  and  $l$  all even. This fact is characteristic  
19  
20 of a pure  $A2$  Heusler structure [38], within which the Co, Fe and In sites are disorderly distributed  
21  
22 into the cubic crystalline structure of the  $\text{Co}_2\text{FeIn}$  nanowires. For  $B2$  and  $L2_1$  structures, reflections  
23  
24 satisfying the condition  $h + k + l = 4n + 2$  with  $h$ ,  $k$ ,  $l$  all even are also expected. Additionally, odd  
25  
26 superlattice reflections (with  $h$ ,  $k$  and  $l$  all odd) is only expected for the  $L2_1$  structure [38].  
27  
28  
29  
30  
31  
32  
33

34 XRD pattern of the  $\text{Co}_2\text{FeIn}$  nanowires array shown in the Figure 4 c), confirmed the results  
35  
36 obtained from the SAED analysis. Three well-defined peaks are observed at  $44.4^\circ$ ,  $64.6^\circ$  and  $81.8^\circ$ ,  
37  
38 which can be indexed as the diffractions coming from the (220), (400) and (422) planes of a  
39  
40 Heusler phase of the  $\text{Co}_2\text{FeIn}$  alloy with a lattice constant  $a = 5.764 \pm 0.001 \text{ \AA}$ . The coherence  
41  
42 lengths obtained from these diffraction peaks using the Scherrer formula [56], (13, 11 and 10 nm,  
43  
44 respectively), are significantly smaller than the dimensions of the nanowires, indicating that  
45  
46 nanowires are polycrystalline. On the other hand, the dominant (220) diffraction peak indicates  
47  
48 that the  $\text{Co}_2\text{FeIn}$  nanowires exhibit a crystalline texture with the [110] direction along the long axis  
49  
50 of the nanowires, in agreement with the HR-TEM results. Moreover, a very small peak ascribed  
51  
52 to the diffraction of the (111) planes corresponding to the fcc phase of metallic gold appears at  
53

### 10 **3.3 Magnetic behavior of $\text{Co}_2\text{FeIn}$ nanowires**

11  
12  
13 In order to determine the whole magnetic behavior of the  $\text{Co}_2\text{FeIn}$  Heusler alloy nanowires in  
14 the arrays, the magnetic hysteresis loops were measured in both, parallel and perpendicular  
15 directions of the applied magnetic field with respect to the nanowires axis, at the temperature of  
16 10 K (Figure 5 a). The parallel and perpendicular hysteresis loops displayed in Figure 5 a, which  
17 are normalized by the maximum signal at saturation of the magnetization ( $M_S$ ), show a noticeable  
18 tilting towards increasing applied field values that is usually ascribed to the magnetostatic dipolar  
19 interactions among the nanowires in the array [26]. The squared shape of bulk magnetic hysteresis  
20 loop carried out in the parallel direction to the nanowires axis, points to the fact to a more bistable  
21 magnetic behavior whose easy magnetization axis lies parallel to the nanowire's longitudinal  
22 direction. Domain wall propagation dominates in this axial direction, as confirmed also by MOKE  
23 measurements carried out in single isolated nanowires.  
24  
25  
26  
27

34  
35  
36  
37  
38  
39

40 The bulk hysteresis loops of the nanowire arrays measured in the perpendicular direction reveal  
41 that the magnetization rotation process becomes dominant along this hard magnetization axis. In  
42 this last direction, the magnetization begins to saturate at higher value of the applied magnetic field  
43 (7 kOe) in comparison to the hysteresis loop measured along the parallel direction (3 kOe). This  
44 fact indicates an anisotropic behavior where the easy magnetization axis may be close to the  
45 parallel direction to the nanowires axis. Coercive field ( $H_C$ ) of nanowires array for both applied  
46 magnetic field directions are also enhanced in the inset shown in the panel below. It can be clearly  
47

2  
3 seen that coercivity measured at 10 K along the parallel direction to the nanowires axis reaches  
4  
5 higher value (~265 Oe), than in the perpendicularly magnetized direction (~1.5 Oe), what also  
6  
7 indicates that the easy magnetization axis of the Co<sub>2</sub>FeIn alloy nanowires array lies along the  
8  
9 nanowires length. This fact is due to the combined effects of the dominant role played by the  
10  
11 magnetostatic shape anisotropy of the high aspect ratio (length/diameter) cylindrical nanowires,  
12  
13 together with the crystalline texture along the [110] direction observed by XRD and HR-TEM in  
14  
15 the polycrystalline nanowires.

15  
16

17 One of the crucial parameters that describes the magnetic properties of any magnetic system is  
18 its magnetic anisotropy, which is characterized by the anisotropy field,  $H_a$ . The anisotropy field  
19 distribution (AFD) can be easily determined from the magnetic hysteresis loops measured in the  
20 perpendicular direction with respect to the wires axis. Considering the magnetization curve of each  
21 nanowire, measured perpendicularly to the easy magnetization axis, which saturates at the  
22 anisotropy field value,  $H_a$ , the second order derivative of the magnetization curve gives the  
23 distribution of the anisotropy field [57, 58].  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33

34 According to this method, the anisotropy field distribution,  $P(H_a)$ , can be deducible from the  
35 positive descendent branch of the perpendicular hysteresis loop between saturation and remanence,  
36 detected in the perpendicular direction to the easy magnetization axis:  
37  
38  
39  
40  
41

$$P(H_a) = -H \frac{d^2}{dH^2} \langle M(H) \rangle |_{H=H_a}, \quad (1)$$

42  
43  
44  
45

46 where  $M$  is the magnetization and  $H$  is the applied field [57, 58].  
47  
48

49 Figure 5 b) shows the isothermal magnetization curves and their corresponding anisotropy field  
50 distributions,  $P(H_a)$ , obtained at different temperatures, for the Co<sub>2</sub>FeIn Heusler alloy nanowires  
51 when the magnetic field was applied perpendicularly to the nanowires length. The  $P(H_a)$  obtained  
52  
53

58  
59  
60

1  
2  
3 from the hysteresis loop measured at 10 K shows a symmetric shape with a maximum at 6234 Oe  
4 and a full width at half maximum (FWHM) of 2468 Oe. With the increase of the temperature, the  
5  
6  
7 peak of the anisotropy distribution shifts to lower magnetic field value, which has been similarly  
8  
9  
10 observed in nanostructured systems [59]. The temperature dependence of the maximum of the  
11  
12 P(Ha) distribution, together with the coercive field,  $H_C$  (measured in the parallel direction), and  
13  
14 saturation magnetization,  $M_S$ , are also plotted in Figure 5 c). The similar decrease observed for  
15  
16 these three magnitudes (P(Ha),  $H_C$ ,  $M_S$ ) with the temperature suggest the same origin, which can  
17  
18 be explained in terms of the homogenization of the effective magnetic anisotropy. Small variations  
19  
20 may be caused by the thermomagnetic evolution of the saturation magnetization. The origin for  
21  
22 the temperature dependence of the effective magnetic anisotropy and coercivity should reflect the  
23  
24 compromise of the temperature dependence for the overall magnetic anisotropy energy  
25  
26 contributions namely, magnetoelastic, magnetocrystalline and shape or magnetostatic terms,  
27  
28 where the most relevant role would be played by the magnetocrystalline and magnetoelastic  
29  
30 anisotropy terms. In the last case, it has to be considered two contributions for the magnetoelastic  
31  
32 coupling, the temperature dependence of the magnetostriction coefficient of the metallic alloy and  
33  
34 that of the mechanical stress arising from the different thermal expansion coefficients between the  
35  
36 metallic nanowires and the ceramic alumina template. On cooling, the metallic nanowires tend to  
37  
38 contract faster than the ceramic alumina template, thereby giving rise to induced radial tensile  
39  
40 mechanical stress, which result in an increasing of the uniaxial anisotropy parallel to the nanowires  
41  
42 axis [29, 60].  
43  
44  
45  
46  
47  
48  
49

50 Additionally, the temperature dependence of saturation magnetization,  $M_S(T)$ , of  $\text{Co}_2\text{FeIn}$   
51  
52 Heusler nanowires shown in Figure 5 c), exhibits the ordinary ferromagnetic behavior. The Curie  
53  
54 temperature ( $T_C$ ) was found to be well-above our experimental setup and room temperature, which  
55  
56  
57  
58  
59  
60

1  
2  
3 is in a good agreement with the  $T_C$  values of other  $\text{Co}_2\text{Fe}$ -based Heusler compounds ( $\sim 1000$  K)  
4  
5 [61].  
6

7  
8  
9 On the other hand, there are some experimental works dealing with the magnetic properties of  
10  
11  $\text{Co}_2\text{Fe}$ -based Heusler alloys having similar compositions. Alloys in the form of bulk that were  
12  
13 prepared by means of different experimental methods like electrochemical deposition ( $\text{Co}_2\text{FeSn}$ )  
14  
15 [62], arc melting ( $\text{Co}_2\text{FeSi}$ ) [63], and melt spinning ( $\text{Co}_2\text{FeSi}$ ) [64], exhibit a comparable soft  
16  
17 ferromagnetic behavior with low  $H_C$  values ranging up to 100 Oe.  
18  
19  
20

21  
22 In order to determine also the magnetic behavior of a single isolated  $\text{Co}_2\text{FeIn}$  nanowire,  
23  
24 magneto-optical Kerr effect (MOKE) technique has been used. The intrinsic magnetic behavior of  
25  
26 single, isolated nanowires may be determined by measuring their hysteresis loops using the  
27  
28 magneto-optical Kerr effect. This technique allows for characterizing isolated  $\text{Co}_2\text{FeIn}$  nanowires  
29  
30 without considering the effect of strong magnetostatic dipolar interaction that take place in densely  
31  
32 packed nanowire arrays. In addition, hysteresis loop measurements performed by MOKE on single  
33  
34 freestanding nanowires under different temperatures could provide an approached method for  
35  
36 unveiling the different contributions to the magnetothermal behavior induced by magnetoelastic  
37  
38 effects that appear in nanowire arrays embedded in AAO templates [60, 65], which could be  
39  
40 subject of future works.  
41  
42  
43  
44

45  
46 Figure 6 a) displays a representative example of the longitudinal MOKE hysteresis loops  
47  
48 obtained for single isolated  $\text{Co}_2\text{FeIn}$  alloy nanowires. The shape of the loops is similar to that  
49  
50 previously reported in Co-rich nanowires [25], and it is characterized by a competition between  
51  
52 shape and magnetocrystalline anisotropy contributions that lead to a complex magnetization  
53  
54 reversal process.  
55  
56  
57  
58  
59  
60

**Figure 6:** (a) Longitudinal MOKE hysteresis loops of a single  $\text{Co}_2\text{FeIn}$  Heusler alloy nanowire measured at RT. (b) Switching field,  $H_{sw}$ , distribution obtained from MOKE measurements for a population of over 50 single isolated  $\text{Co}_2\text{FeIn}$  Heusler alloy nanowires.

In first place, the magnetization progressively decreases from saturation, suggesting local magnetization rotation processes as the applied magnetic field is reduced. Then, the magnetization of the nanowire switches in a single jump to the opposite value to that of the initial state. The switching field distribution ( $H_{sw}$ ), was obtained from the measurement of about 50 independent nanowires, as shown in Figure 6 b). The dispersion in switching fields,  $H_{sw}$ , could be understood in terms of different factors, such as small variations in diameter and length between different nanowires. Nevertheless, a Gaussian-like distribution is found, with a mean value of  $\langle H_{sw} \rangle = 124$  Oe and a FWHM of 27 Oe. The mean value of the switching field as measured by MOKE,  $\langle H_{sw} \rangle$ , is slightly larger than the coercivity,  $H_c$ , of the array of nanowires measured at the same temperature by SQUID, which takes a value of 85 Oe. This apparent discrepancy has been previously found in ferromagnetic nanowires and it is linked to the strong magnetostatic interactions that take place among neighboring nanowires in the array [25, 66].

#### 4. Conclusions

1  
2  
3 In summary, we report on the first electrochemical synthesis of ternary  $\text{Co}_2\text{FeIn}$  Heusler alloy  
4 nanowires, which are fabricated by a simple template-assisted electrodeposition method in H-AAO  
5 membranes. This template-based method of synthesis is a facile approach for obtaining large  
6 amounts (in the order of  $10^9$  nanowires/ $\text{cm}^2$ ) of dense metallic arrays of Heusler based nanowires  
7 with high aspect ratios, having a mean diameter of about 180 nm and around 14.5  $\mu\text{m}$  in length.  
8 The EDS elemental mapping analyses reveal that the chemical compositional distributions of the  
9 elements (Co, Fe, In) is very uniform along the nanowires length. HR-TEM, SAED and XRD  
10 analyses confirmed that the  $\text{Co}_2\text{FeIn}$  alloyed nanowires exhibit a polycrystalline character, having  
11 a cubic  $A2$  disordered Heusler structure with a lattice parameter of  $5.764 \pm 0.001 \text{ \AA}$  and (220)  
12 texture. Magnetic measurements, performed on both, nanowire arrays or single isolated and non-  
13 interacting nanowires, revealed their soft ferromagnetic behavior, where the magnetization  
14 rotation process dominate near saturation of magnetization and having the easy magnetization axis  
15 lying parallel aligned to the nanowires long axis, with the Curie temperature well-above the room  
16 temperature. As discussed before, the easy and low-cost preparation method of Heusler alloy  
17 nanowires via template-assisted electrochemical deposition is a promising and new forward-  
18 looking fabrication of Heusler nanomaterials for their applications in many research fields such as  
19 in spintronics and magnetic data recording.
